User's Guide and Documentation of  
the ONAC Railroad Cash Flow Model

May 28, 1981

RAILROAD CASH FLOW MODEL  
Summary

Acronym: CABOOSES  
Media/subject: Noise

MODEL OVERVIEW: The Railroad Cash Flow Model estimates the discounted present value of each firm's future cash flow stream. To determine this, the net worth of each railroad firm is subtracted from the present value of future cash flow.

The model was developed by contractor in order to perform the economic analysis for the railroad regulation. The model was implicitly developed through contract funding but is not currently available for use on EPA's computer system.

FUNCTIONAL CAPABILITIES: Two versions of the model exist. They support different revisions of proposed railroad regulations.

BASIC ASSUMPTIONS: N/A

COMPUTATIONAL SYSTEM REQUIREMENTS:

Hardware: Mainframe not yet determined  
Disc storage not yet determined  
Language: FORTRAN

## SECTION I - DESCRIPTION OF THE CASH FLOW MODEL

### Introduction

This section describes the cash flow model used in the financial analysis in support of the railroad yard noise standard and conducted for the Background Document. Included in this section is an explanation of the purpose of the model and the derivation of the equations used in the model. Data inputs are listed and a sample of the output tables is subsequently shown.

### Cash Flow Model

The methodology of the cash flow model is that presented in the original EPA Background Document for EPA/ONAC titled "Background Document for Final Rail Carrier Noise Emissions: Source Standards, December 1979." The methodology uses the net present value or discounted cash flow technique to assess the financial impact of noise abatement costs on each of 56 railroads. The net present value (NPV) of each railroad's 20-year (1980 to 1999) stream of cash flow in the absence of noise abatement is compared to the NPV of noise abatement costs plus net investment over the same period of time. Cash flow is defined as the sum of net income after interest and federal income taxes plus depreciation and amortization, and deferred taxes, less the equity in earnings of affiliated companies. Current net investment is defined as net worth, the difference between assets and liabilities. It is composed of capital stock, capital contributions, and retained earnings. Net worth represents that portion of assets or investments which are owned by the company and not by creditors.

Adjusted cash flow is cash flow without depreciation added back into

the calculation. The rationale for computing an adjusted cash flow is to allow for some cash outflow for capital expenditures not related to the noise regulation. It is assumed that depreciation is an approximate measure of capital expenditures that are not related to noise regulations. A further discussion of this assumption is contained in a section below describing the parameters of the model.

The cash flow analysis operates by subtracting the net worth (NW) of each railroad from its discounted present value of future cash flows (DCF). The NW of the firm is the original cost of its net assets. The firm's DCF is equal to the sum of its yearly cash flows discounted by the opportunity cost of capital, that is, the rate of earnings that capital would bring in its next most productive use. DCF is then the present value of the cash that the firm's net assets would generate. The difference between DCF and NW is referred to as the net present value of future cash flows (NPV). When the net present value of abatement costs plus the net worth is greater than or slightly less than cash flow or where abatement costs seem large relative to cash flow, potential financial difficulty for that firm may be present.

The cash flow model computes the NPV before and after the noise regulation in order to determine the magnitude of regulatory burden. In order to provide a common measure to compare the financial health of different sized firms, the NPV of each firm is divided by its own NW. This allows a comparison of firms of different sizes according to their financial condition. Changes in that ratio after regulation provide an indicator of the compliance burden which can be compared across (different sized) firms.

The following broad categories were used to evaluate firms according to their ratio of NPV/NW.

(1) Weak Firms

If the NPV/NW < 0.0, the firm is in very weak financial condition. Noise abatement expenditures will worsen or create a tenuous financial condition

(2) Marginal Firms

If zero is less than NPV/NW, it is less than 0.1 before or after abatement expenditures, the firm may suffer significantly due to the regulation.

(3) Strong Firms

If NPV/NW is greater than 0.1 after the regulation, the firm has a reasonably sound financial structure, and regulation will probably not cause major financial difficulties.

Description of the Present Value Analysis

A number of assumptions are necessary in order to carry out the present value analysis. They include the following:

1. Time horizon for analysis is 20 years beginning January 1st 1980 and ending on December 31st 1999.
2. The annual inflation rate is 6%.
3. The discount rate chosen for present value analysis is 10%.
4. The marginal tax rate is 46% which is the marginal tax rate for corporate income above \$100,000 for years beginning after 1978.
5. Pollution abatement equipment is depreciated by the straight line method with a zero salvage value. Equipment is replaced when fully depreciated except for mufflers for switcher engines. Replacement mufflers represent a current maintenance expense after the initial muffler is worn out (in accordance with ICC accounting principles).

6. All pollution abatement equipment qualifies for investment tax credit. The tax credit is equal to 10% of capital expenditure. It is assumed that the full investment tax credit will be taken in the year in which equipment is acquired and put into use.

#### Computations

The computations that are made in the cash flow model are relatively straightforward. The main result of the model, the ratio of NPV to NW for each firm is determined through a series of equations which may be summarized in the following steps.

##### Step 1 - Cash Flow Determination

The 1973 through 1978 average is used as the first observation in the annual stream beginning in 1980. It is defined as net income after taxes, interest and extraordinary items, plus deferred taxes, less equity of earnings of affiliates. Depreciation is not added back in the baseline cash flow estimates. Cash flow is defined as

$$CF = NI + DEFT - EQ$$

where CF is cash flow, NI is net income, DEFT is deferred taxes, and EQ is equity and earnings of affiliates. For each railroad the cash flow average was inflated by 6% per year to account for inflation, discounted by 10% a year to calculate the present value, and summed to derive the net present value of the 20-year stream of cash flows.

Net worth is calculated as the average over the period 1973 to 1978 and is termed "average net investment."

Step 2 - The net present values of future cash flows are calculated by reducing the present values of future cash flows by average net investment

or net worth. This is done on a railroad by railroad basis and those railroads that display a negative net worth are eliminated from further net present value analysis. However, their abatement cash flow change is calculated.

Step 3 - Capital expenditures detailed by noise source for each railroad are shown in the year in which the expenditure is made. The cost of each treatment that is applicable to each noise source is multiplied by the number of sources. The equipment is replaced when fully depreciated and additional capital expenditures are made. Present values of capital expenditures are computed by inflating the expenditures by 6% a year from 1980 on and discounting back to the present at a 10% discount rate.

Step 4 - Noise related operations and maintenance expenditures, out-of-service, and depreciation costs are computed for each year using the O&M and out-of-service cost estimates for each source, and capital expenditure and useful life data for each fix applicable to each source. The effect of taxes is evaluated in the analysis with before-and after-tax costs being determined. Operation and maintenance expenditures and out of service costs, have an after-tax cost of  $1-T$ , that is 1 minus the tax rate. Depreciation has a tax "shield" in the sense of cash flow equal to tax depreciation expense. These costs are separated by source before and after taxes and are totaled for each railroad. They are presented in 1979 dollars.

Because the abatement cost data are to be used in the cash flow analysis, they must be adjusted for the impact they have on cash flow. Out of service costs, treated as a period cost with the same tax impact as O&M, are included hereafter in the general discussion of O&M costs.

In an abatement scenario, adjusted cash flow is reduced by the additional

O&M costs offset somewhat by the reduction of taxes which arise because of the reduced net income (from the increased O&M costs), that is,

$$\begin{aligned}\Delta CF_{O\&M} &= -\Delta O\&M + T(\Delta O\&M) \\ &= -\Delta O\&M (1-T)\end{aligned}$$

where T = tax rate.

In addition, increased depreciation also changes baseline cash flow. Depreciation is a non-cash expense which reduces taxes and thus has a positive effect on cash flow. Initially,

$$\begin{aligned}\Delta CF_{DEP} &= -\Delta DEP + T(\Delta DEP) \\ &= -\Delta DEP (1-T)\end{aligned}$$

where again, T is the tax rate.

However, a basic premise in cash flow analysis is that flows are considered, not accounting charges and credits. Thus, all non-cash items are added back to after tax net income. Thus,

$$\begin{aligned}\Delta CF &= -\Delta O\&M (1-T) + [-\Delta DEP (1-T)] + \Delta DEP \\ \Delta CF &= -\Delta O\&M (1-T) - \Delta DEP (1-T) + \Delta DEP\end{aligned}$$

which reduced,

$$\Delta CF = -\Delta O\&M (1-T) + \Delta DEP (T)$$

Step 5 - Investment tax credits generated by capital expenditures are treated as an annual item to increase cash flows. Investment tax credits are taken at the full rate of 10% of capital expenditure. They are taken in the year in which the asset is acquired and assumed put in place. It is assumed that there are no limitations on investment tax credits and all equipment is eligible for the full tax credit.

Step 6 - The aggregate change in cash flow is derived by increasing  $\Delta CF$  by the investment tax credit in those years in which equipment is acquired. The present value is computed for each year by applying the present value factor and summing the stream of incremental cash flows. Thus,

$$\Delta CF = - \Delta O\&M (1-T) + \Delta DEP (T) + ITC$$

$$PV \Delta CF = \sum_{i=1}^{20} PV (- \Delta O\&M_i)(1-T) + \Delta DEP_i(T) + ITC_i$$

where PV = present value and ITC corresponds to the investment tax credit.

Step 7 - The net present value of abatement cash flow is determined by reducing the present value of change in cash flows by the present value of the capital expenditures. Thus,

$$NPVACF = PV\Delta CF - PVCAP$$

$$NPVACF = \sum_{i=1}^{20} [PV (- \Delta O\&M_i (1-T) + \Delta DEP_i (T) + ITC_i)] -$$

$$\sum_{i=1}^{20} PVCAP_i$$

where NPVACF is net present value of abatement cash flow; PVCAP is present value of capital expenditures and all other variables are defined as above. The net present value of change in abatement cash flows by yard type for each railroad is presented in the analysis.

Step 7 - The net present value of abatement cash flows is subtracted from the net present value of future cash flows, leaving the net present value of future cash flow with abatement. Thus,

$$NPV = NPVFCF - (-NPVACF)$$

$$NPV = NDVFCF + NPVACF$$

where NPVFCF is net present value of future cash flows, NPVACF is net

present value of abatement cash flows.

Step 8 - The net present value of abatement cash flows is compared to the net investment for average net worth. If the net present value is positive, a relatively small potential financial difficulty may be present. With this analysis, relatively small is interpreted to mean a difference which is positive but less than 10% of net worth. For railroads with a positive difference greater than 10%, future analysis is suggested only if abatement costs appear unusually large relative to other data. The ratio is calculated by dividing the net present value of cash flows after abatement by net worth, as explained above.

#### Data Inputs

The operation of the cash flow model depends upon a number of data files as input. These data files contain all the key inputs and parameters of the model. The parameters are easily accessed through the data files and thus the model is easily updated and changed.

The data includes 6 years, 1973 through 1978 of historical data for the following relevant financial items which are taken from the ICC forms R-1 and R-2, annual reports.

1. Income (from the Income Statement)
  - a. Net railway operating incom
  - b. Income after fixed charges
  - c. Ordinary income (operating income)
  - d. Net income (after extraordinary items, accounting changes, and discontinued operations)
2. Depreciation and amortization (from operations)(from the Statement of Changes in Financial Position)
3. Deferred taxes (from the Statement of Changes in Financial Position)

4. Undistributed equity in earnings of affiliated companies (from either the Income Statement or the Statement of Changes in Financial Position)
5. Net worth (from the Comparative Balance Sheet as net shareholder's equity)

The data are contained in the file.RRDATA, in the order listed above for each railroad by alpha code for each of the six years. Additionally, data items representing cash dividends paid and equipment expenditures were collected and are stored for most railroads. However, these items are not used in the current version of the program.

The model was developed to allow flexibility when analyzing various combinations of regulatory assumptions. This is reflected in the parameters specified in the .FACTORS file. When the regulatory scenario assumptions change, a new file is created: for example .FACTORS1, .FACTORS2, etc. These parameters are listed below, then discussed in greater detail:.

1. Inflation Rate
2. Discount Rate
3. Tax Rate (marginal corporate tax rate)
4. Investment tax credit (rate)
5. Option (regulatory option)
6. PVCE Detail RPT (present value of captial expenditures detailed report)
7. DEP EXP Detail (depreciation expense detail)
8. Number of Fixes
9. Income Usage
10. Number Years
11. FACTOR1
12. FACTOR2
13. FACTOR3

1. Inflation Rate is that rate assumed to affect railroad costs and revenues. It is incorporated into the model in the discounting process. The inflation rate is used to compute the future value. Only cash flows are adjusted for inflation. The rate chosen is 6%.

2. Discount Rate is that rate used to compute the present value from the future value. The discount rate is not itself adjusted for risk or inflation. The rate chosen is 10%.

3. Tax Rate, as used here, is the current marginal corporate rate (46%). This can be changed to reflect effective rates.

4. Investment TCR (investment tax credit rate) is applied to all capital expenditures imposed by the regulation. The full investment credit is assumed to apply; that is, the program would not adjust depreciable lives less than seven years in the tax credit. The tax credit is treated as an inflow.

5. Option serves two purposes.

By labelling each report on each page of printout, the option number can be specified to be the .FACTORS file number so as to produce results easily identifiable with the data file and regulatory assumptions. In the final version, option + 11 indicates only residential receiving line impacts. Option + 12 indicates residential and commercial receiving line impacts.

An option number greater than zero specifies that depreciation will be considered as a non-cash expenditure and thus added back in the standard cash flow equation. An option number less than zero specifies that depreciation will not be added back in the cash flow equation. The rationale for developing this "non-standard" flexibility rests on the assumption that nonregulatory recurring capital equipment outlays will approximate annual depreciation charges.

6. The PVCE detail report will be printed for each railroad when the number specified in the .FACTORS file is not zero. These detailed reports will not be printed when zero is specified.

7. Similarly, the depreciation expense detail report can be printed or not printed with the specification of a number not zero or zero, respectively.

8. Number of Fixes is the maximum number of separately cost identifiable technology fixes for any noise source to comply with the regulation. It is the sum of separate technologies for a noise source for all stages of the regulation. The first three fixes are Phase 1 technologies and costs, and the last three are Phase 2.

9. By stating the income usage in the .FACTORS file, the appropriate net income is specified which is taken into the cash flow computation. The income usage numbers can be any of the following: 1, for net railway operating income; 2, for income after fixed charges; 3, for ordinary income; and 4, for net income. These data are included in the historical data base and further explanation is given in that section.

10. Number of years specifies the number of years of historical data which will be taken to compute the average. The average is then used as the baseline (1979) financial items taken in the net present value model.

11. FACTOR1 is the estimated percentage of total identifiable retarders impacted by the regulatory option (i.e., noise sources at residential receiving lines only or noise sources at residential and commercial receiving lines).

12. FACTOR2 is the estimated percentage of total identifiable load cell test sites impacted by the option.

13. FACTOR3 is the estimated percentage of total identifiable switcher engines impacted by the option.

The FACTORS file also contains the following input data for each noise source.

Capital expense per unit by fix in the year prior to the date of compliance is replaced where applicable. The cost estimate is given in thousands of dollars.

Annual operating and maintenance cost per unit associated with the technology fix for which equipment is required for compliance. Operating and maintenance costs are claimed through the depreciable life of the equipment. Data are entered in thousands of dollars.

Out-of-service cost per unit is entered where applicable for the noise source and year in which it occurs. This "opportunity" cost is expressed in thousands of dollars.

For all the above, it is necessary that the data file contain a zero value when, in any given year, there is no cost associated with the fix for that noise source. Because switcher engine compliance technology is assumed to be phased in over a four-year period (1980 to 1983) a phase-in factor was developed to spread cost for the total identified number of units impacted by the regulation over the phase-in period. Once the equipment is brought into service, it incurs operating and maintenance costs and could incur out-of-service cost. As a result, phase-in factors are entered for each noise source.

Capital expenditures phase-in factors appear for each applicable fix (for which the cost was previously entered) as the percentage of total units impacted for a specific year.

Operating and maintenance phase-in factors reflect the percentage of new units and their fixes brought into service in a year, in addition to those units and their fixes brought into service prior to that year. This factor is cumulative. Further, if replacement of original equipment is considered, a current or operating and maintenance cost and the original equipment was phased in, this schedule must repeat for each life cycle.

Out-of-service costs, although not occurring on a phased schedule in the current model, can be phased-in. The appropriate factor would be entered in what is now an ineffective file (that is, all phase-in factors for each noise source's out-of-service phase-in factor is 1).

Each phase-in factor file is treated similar to the cost estimate file in that some value must be entered for each source's fix for each year. Where no phasing-in occurs, the factor is unity.

### Model Outputs

The cash flow model produces several distinct sets of results. In addition to calculating the net present values, summary reports are printed which contain the following information for each railroad and the total of all observed railroads.

1. railroad name and number and type is noise source (Table 2)
2. present value factors (Table 4)
3. present value of future cash flows (Table 5),
4. average net investment (average net worth) (Table 5),
5. net present value of future cash flows (Table 5),
6. abatement capital expenditures with replacement (current dollars) (Table 6),
7. present value of abatement capital expenditures with replacement (Tables 7),
8. initial capital expenditures (current dollars)(Table 8),
9. O&M costs before and after taxes (current dollars)(Table 9),
10. out-of-service costs before and after taxes (current dollars) (Table 10),
11. depreciation expense before and after taxes (current dollars)(Table 11),
12. investment tax credit (current dollars)(Table 12), and
13. present value of incremental abatement cash flows and resulting net present values with abatement (Table 13).

Summary tables are also printed which identify the following:

1. railroads with a positive NPV (Table 14),
2. railroads with a negative or zero NPV (Table 15),
3. railroads with  $0 < NPV/NW < 0.1$  (Table 16)
4. railroads with  $NPV/NW > 0.1$  (Table 17)
5. railroads with  $NPV/NW < 0.0$  (Table 18)
6. railroads with a positive baseline future cash flow (Table 19),
7. railroads with a negative baseline future cash flow (Table 20),
8. railroads with positive average net investment (net worth)(Table 21),
9. railroads with negative average net investment (net worth)(Table 22),
10. railroads with positive NPU of future cash flows before abatement (Table 23),
11. railroads with negative NPU of future cash flows before abatement (Table 24),
12. railroads and equipment for each flow analysis (Table 25)

The resulting set of tables are included for illustration purposes only to show the degree of detail produced by the model.

### Overview of WYLBUR and the Cash Flow Model<sup>1</sup>

The Environmental Protection Agency's Washington Computer Center uses an operating system called WYLBUR in which files and programs can be edited at the terminal in an interactive mode. To run a program, it is placed in a queue with other programs (these are known as jobs) and the computer runs one at a time. The parameters and data used by the cash flow model can be changed interactively, but the model must be run in a batch mode. As a result, model parameters cannot be changed while the program is running.

An important feature of the WYLBUR system is the concept of a workspace. A workspace is a temporary storage area in which files can be edited. Only one file may be introduced into the workspace at a time. To preserve editions of a file permanently, the edited file must be saved by writing in onto the computer's disk. Saving an edited file destroys the old version if it is stored under the same name. Multiple versions of a file can be preserved, however, by saving each version under a different file name.

Because WYLBUR does not allow inputs to be changed interactively, a user must modify the key financial parameters before the program is run. These parameters are stored in a data file.

### Accessing the Model

Instructions in Job Control Language which command the computer to run the Railroad Cash Flow Model would be contained in a program called

---

<sup>1</sup>The computer access procedures described here were those in effect during the development and initial implementation of the model. Periodically those procedures change and the user should contact technical support and appropriate EPA personnel for assistance in using the system. JCL procedures should remain as they appear here regardless of changes to computer access.

"CN.EPAJHU.S2KC.CABOOSES". Once the program has been put up on the computer, it is accessed by logging onto the WYLBUR system of the EPA's Washington Computer Center (WCC).

Accessing the system consists of two steps:

1. getting through the telecommunications network to WYLBUR
2. logging on to WYLBUR

Step 1 is a fairly mechanical process and is described in flow chart form (see Figure 1).

Note: The flow chart is not foolproof. For example, if you can't get the high-frequency tone in two tries, you should try again using another telephone number.

Configuration of the computer terminal:

Main power switch: ON

Modem power switch (if separate): ON

Mode: HALF DUPLEX

Baud rate: 300

Terminal mode: LINE

NOTE: <CR> means carriage return.  
Resp: means user response.

Step 2. If everything in Step 1 goes right, the following message is received:

INVALID SYSTEM

Resp: WYL<CR><sup>1</sup>

READY TO WCC ON sss<sup>2</sup>

---

<sup>1</sup>Log on to the WYLBUR system.

<sup>2</sup>sss is the system number.

ILLEGAL TERMINAL TYPE

Resp: <CR>

MODEL 37/38 TELETYPE

WYLBUR SYSTEM AT COMNET PORT xx today date time<sup>3</sup>

Resp: USERID ? EPAlII<CR><sup>4</sup>

Resp: ACCOUNT ? AAAA<CR><sup>5</sup>

Resp: PASSWORD ? Pppppppp<CR><sup>6</sup>

SPECIFY GLOBAL FORMAT FOR SAVE COMMANDS.

REPLY - DEFAULT, EDIT, TSO, CARD, OR PRINT

Resp: FORMAT? CARD<CR><sup>7</sup>

COMMAND?

This ends Step 2.

Access to CN.EPAJHV.S2KC.CABOOSES may be obtained by typing:

USE \$CN.EPAJHV.S2KC.CABOOSES<CR>

Note: If the computer responds by typing VOLUME? and you have typed the instruction properly, this means that the cash flow model is no longer available on-line. WCC has stored the cash flow software off-line because it has not been used in more than 2 months. The question VOLUME? asks where the software is located.

To run the cash flow model, type:

RUN NOTIFY<CR>

<sup>3</sup>'xx' is the port number.

'today' is today's day of the week.

'date' is today's date.

'time' is the time you succeeded in logging on to WYLBUR.

<sup>4</sup>'EPAlII' is your userid

<sup>5</sup>'AAAA' is your user account code

<sup>6</sup>'pppppppp' is your password

<sup>7</sup>Choose one of the above formats

{ Check with  
your EPA  
project officer

Notify instructs the computer to inform the user that the program has been run.

The computer will respond by typing:

XXXX IS YOUR JOB NUMBER.

where XXXX will be some three- or four-digit job number. Usually between 5 and 30 minutes pass before the program is run. To determine whether the program has been run yet, type:

LOC XXXX

where XXXX is your job number. If the computer responds:

JOB XX IN OUTPUT HOLD

then the job output is ready.

One can leave the system while waiting for the program to run. Instructions on how to leave the system are presented below.

Once the program has been run, one may fetch the output. This is done by typing

FETCH XXXX<CR>

where XXXX is the job number described above.

The computer will reply:

OK TO CLEAR?

This message asks whether the computer can empty the user's workspace to bring the job output in. In this manner, the system seeks to avoid destroying edited files one might wish to save.

The user should respond: YES<CR>

This will bring the cash flow output into the user's workspace.

To list the output, type:

```
LIST<CR>
```

The first XXX lines of output will be extraneous material generated by the computer and not relevant to the user of the model. To print out only the necessary output, type:

```
LIST XXX/XXXX CC UNN
```

which instructs the computer to print lines XXX to XXXX of the file, which includes all the relevant output. CC means to use the first character of each line as a carriage control. UNN means to print each line without its WYLBUR-generated line number.

To leave the system, type:

```
CLEAR TEXT<CR>
```

which clears the user's workspace, and then type:

```
LOGOFF<CR>
```

which terminates contact with the system.

Then hang up the telephone.

The system editor can be used to modify any of the parameters or data that were described in the previous sections of this report. Each modification should be saved in a separate file for later reference. The user should refer to a standard WYLBUR manual for instructions on how to change data and vary parameters.

APPENDIX A

### Railroad Cash Flow Model - User's Guide

The Railroad Cash Flow Model, called CABOSES, was originally contained on the alpha system at COMNET. Subsequent changes to the EPA computer system require that any further use of CABOSES be made on the EPA computer system now housed at Research Triangle Park and using the WYLBUR system. It is recommended that the user read and become familiar with the WYLBUR guide which will allow the preservation of the program and data files and the successful manipulation for policy analysis. Appendix A of this report contains a listing of the program and data files necessary to run the Cash Flow Model.

Included in that Appendix are the following:

1. CABOSES - the program which determines the cash flow analysis.
2. FACTORS - a file of parameters used to investigate alternative regulatory options.
3. RRDATA - the initial data base mostly made up of ICC data on specific railroads.
4. INDEX 1 - a railroad dictionary.

The section below presents an overview of WYLBUR and how to run the cash flow model once it has been put up on the system.<sup>1</sup>

<sup>1</sup>This documentation is standardized for all WYLBUR users and was taken from a document prepared by Energy Resources Co., Inc. of Cambridge, Massachusetts that provided software documentation of a different version of the railroad cash flow model that was based on the model explained in the present document.
