## **Special Report**

# Highway Construction Noise: Measurement, prediction and mitigation

AUTHORS JERRY A. REAGAN CHARLES A. GRANT

U.S. DEPARTMENT OF TRANSPORTATION FEDERAL HIGHWAY ADMINISTRATION Office of Environmental Policy PREFACE

In early 1976, the Federal Highway Administration (FHWA) initiated a two-part program designed to study, evaluate and provide guidance in the area of construction noise. Part one was a short-range effort to prepare a manual for use by highway oriented groups and individuals in coping with construction noise during the various stages of project development. The manual would be a state-of-the-art review dealing with measurement, prediction and mitigation. Part two was the sponsorship of a workshop on the mitigation of construction noise. The purpose of the workshop was to develop long-range strategies for controlling construction noise.

This manual represents the completion of part one of the program. This manual does not represent FHWA policy. It is an attempt to summarize the rapidly evolving technology in controlling and mitigating construction noise. This manual represents a logical starting point into the evaluation and control of highway construction noise. Users of this manual are encouraged to update this material as better information becomes available.

#### ACKNOWLEDGEMENT

This manual could not have been prepared without the full cooperation of the Washington Headquarters, with special thanks to reviewers from the Office of Environmental Policy, Office of Highway Operations, Office of Engineering and Office of Research.

The authors especially appreciate the guidance and encouragement given by Mr. Harter M. Rupert, Office of Environmental Policy.

Special thanks is extended to Ms. Beverly J. Williams and Mrs. Juanita B. Proctor for the proofreading and typing of this manual.

#### CHAPTER 1

#### 1.0 BACKGROUND

In our ever expanding quest for an improved environment, we are concerned with the evaluation and control of transportation noise. For several years, Federal, State, and local attention has been directed toward operational noise impacts resulting from the operation and movement of transportation vehicles. Recently, considerable concern, particularly in urban areas, has been focused on the construction noise associated with the development of the transportation facility. This manual deals specifically with the measurement, prediction, and mitigation of highway construction noise.

#### 1.1 EVALUATION AND CONTROL OF CONSTRUCTION NOISE

In order to evaluate and control highway construction noise, the following information must be known:

- 1. The existing noise environment.
- 2. The expected construction noise levels.
- 3. The criteria that relate the existing noise environment and the expected construction noise levels to human responses.
- Mitigation strategies that can be used to control the construction noise.

The first three items are used to evaluate the noise associated with the construction of the highway to see if a noise impact does exist. If a noise impact does exist, the last item provides mitigation strategies that can be used to control construction noise.

#### 1.2 CONSTRUCTION NOISE CRITERIA

Section 1.1 indicated that criteria were needed before construction noise impacts could be quantified in terms of human response. While progress is being made in this area, criteria for evaluating construction noise have not been developed. It appears that several years will elapse before such criteria are established. In the interim, the user of this manual must select his own criteria. In selecting such criteria, the following factors should be considered:

1. The difference between the existing noise environment and the expected construction noise levels.

2. The absolute level of expected construction noise.

3. Adjacent land uses.

The duration of construction.

#### 1.3 NOISE METRIC

While it is not possible to provide criteria for evaluating construction noise impacts, a noise metric must be selected which can be used to describe noise levels. A noise metric to describe construction noise should meet the following criteria:

- 1. It should be an easily measurable quantity.
- It should account for the temporal variations in the noise levels of individual pieces of equipment.
- It should account for the temporal variations in the overall noise level (site).
- 4. It should be an easily predictable quantity.
- It should relate to people's subjective responses to construction noise.

The metric chosen for use in this manual is the hourly, A-weighted equivalent sound level (energy basis),  $L_{eq}(h)$ . This metric satisfies the first four requirements. It may also satisfy the fifth requirement, but there is not enough information presently available to select any metric on this basis.

#### 1.4 MANUAL ORGANIZATION

Chapter 2 discusses noise measurements. Unfortunately, only limited measurements of highway construction noise have been made. The data available in the literature are often quite vague on what noise levels were measured and how they were measured. While measurement procedures are being developed, they have not yet evolved to the point where they have been standardized.

In Chapter 3, a prediction procedure is presented. The prediction procedure describes a method that can be used to calculate the noise levels resulting from a construction operation. It also permits the evaluation of alternative strategies to control the noise level. Chapter 4 discusses mitigation methods and techniques. Methods of lessening the impacts of noise produced by construction activities are outlined, ranging from equipment modification to community awareness. Included in this chapter are examples of regulations or specifications that may be used in controlling construction noise. The sample specifications have been devised and used by various agencies to abate construction noise. In some cases, the construction noise specifications are not strictly highway related, but may be applicable in many situations.

Appendix A lists noise levels for various types of construction machinery. This section gives the reader a very basic indication as to the wide range of noise levels produced by different individual pieces of equipment. It should be noted that the levels provided in Appendix A are peak values based on limited data. Users of this manual are encouraged to supplement, refine, and update these values.

Appendix B provides the measurement procedures referenced in the manual.

#### CHAPTER 2

#### NOISE MEASUREMENTS

#### 2.0 BACKGROUND

Excluding Occupational, Safety and Health Administration (OSHA) requirements, noise measurements related to highway construction are generally made for only one purpose: to obtain information needed to identify, evaluate and mitigate highway construction noise impacts. Basically, three types of information may be needed:

- 1. The existing sound levels in the vicinity of the project prior to the start of construction.
- The sound levels generated by the individual pieces of equipment.
- 3. The overall sound levels associated with the construction of the project.

Obviously, the amount of information needed will vary from project to project. In some environmental assessments, it may be possible to obtain all of the information needed without any measurements.

In this manual, all of the information needed to identify and evaluate highway construction noise impacts is expressed in terms of the hourly, A-weighted, equivalent sound level,  $L_{eq}(h)$ . Although equipment is available that will measure this metric directly, this manual assumes that only a hand-held sound level meter (SLM) is available. Therefore, it will be necessary to record the instantaneous sound levels measured by the SLM and compute the  $L_{eq}(h)$ . This is illustrated graphically in Figure 1.

This approach was chosen for two reasons. First, it was felt that the hand-held SLM was in more common use than the Leq meters among highway agencies. Secondly, standardized measurement procedures for construction noise are now under development by several national and international organizations. Unfortunately, these organizations have not adopted a standard metric to describe construction noise. Use of the Leg(h) permits the use of the measurement procedures that have been developed to date and allows data comparisons to be made using a common metric.

#### Figure 1: Sound Level Versus Time

The remainder of this chapter discusses measurement procedures that can be used to measure the existing sound levels (Section 2.1), the sound levels of individual construction equipment (Section 2.2), and the overall construction sound level (Section 2.3). Each section will define the sound level being discussed, indicate when the measurements are made, what uses are made of the sound levels, and how they are measured.

#### 2.1 EXISTING SOUND LEVELS

Existing sound levels describe the acoustical environment prior to modification of an existing highway or construction of a new one. The existing sound levels include all natural and manmade sounds present at the site.

Information on existing sound levels is routinely developed during the noise studies for a highway project. If the project involves the reconstruction of an existing highway, or if the new project is located near another highway, and if the existing sound levels are predominantly due to highway traffic, the  $L_{eq}(h)$  can be computed. This can be done

using the traffic noise prediction models. In other situations, sound level measurements are needed to quantify the existing acoustical environment. In either case, the information on existing sound levels is normally developed in the early stages of project development, often years before construction of the project is started. In some situations, it may be necessary to reevaluate the existing levels prior to the start of construction.

The existing sound levels serve as a reference where the magnitude of the increase in sound levels, due to some changed highway condition, is indicative of the degree of impact. Construction noise impacts can be expected whenever the expected sound levels significantly exceed the existing sound levels.

Chapter 3 of the text<sup>1</sup>, "The Fundamentals and Abatement of Highway Traffic Noise," discusses environmental or existing noise measurements. Information is provided on the use of sound level meters, the selection of measurement sites and when the measurements should be made. In addition, a detailed measurement procedure is provided for determining and recording the existing instantaneous sound levels. Based upon these sound level observations, a procedure and a criterion are given which insure computation of a statistically valid L10 for the time interval over which the measurements were made. Although this time interval is generally shorter than one hour, it is assumed that the sound levels are constant over one hour and the calculated L10 value is representative of an L10(h).

Once a statistically valid L10(h) has been obtained, the  $L_{\mbox{eq}}(h)$  can be calculated as follows:

 $L_{eq}(h) = 10 \log \frac{1}{N} \sum_{i=1}^{N} n_i 10^{Li/10}$  (2-1)

Where Leg(h) is the hourly, A-weighted, equivalent sound level,

- N is the number of sound level readings taken to obtain a statistically valid L10.
- $n_i$  is the number of sound level readings in the i<sup>th</sup> class.
- L<sub>i</sub> is the level of the i<sup>th</sup> sound level reading taken during the measurement period.

Problem No. 1: Compute the Leq(h) of the sound level readings shown in figure 2.

Problem No. 1: (Continued)

.....

Alternately, the following procedure could be used.

Measured Sound Level L	No. of Occurrences (N)	10 log N	L + 10 lag N	dß Sum (dB addition)
49	8	9	58	
47	27	14	61	64
45	15	12	57	

### Table 1: Alternate Computation of $L_{\text{aq}}$ by dB Addition

L<sub>eq</sub>(h) =dB Sum - 10 log N =64 - 17 = <u>47.dBA</u>

Problem No. 2: Compute the  $L_{eq}(h)$  of the sound level readings shown in Figure 3.

#### 2.2 CONSTRUCTION EQUIPMENT SOUND LEVELS

In this manual, construction equipment sound levels are the sound levels emitted by the equipment under actual field operating conditions.

Construction equipment operates under two primary modes - mobile and stationary. Mobile equipment such as dozers, scrapers, graders, etc., operate in a cyclic fashion in which a period of full power is followed by a period of reduced power. Stationary equipment can be subdivided into two groups. One group contains such items as pumps, generators, compressors, etc., and generally operates at a fixed power and produces a fairly constant sound level under normal operation. The other group contains impact equipment such as pile drivers, jackhammers, pavement breakers, etc. Figure 4 shows typical idealized graphs of instantaneous sound levels as a function of time under field operating conditions for each group. This figure also indicates that the variations in sound levels are actually a function of the work cycle.

Data on equipment sound levels can be obtained by two methods: review of current technical publication and by measurements. Information on equipment sound levels being published in technical publications should be used with caution. These values are often peak values and must be adjusted to account for the variations in sound levels over the work cycle. Appendix A presents information on peak sound levels developed by the American Road Builders Association (ARBA). These values, once they are converted to  $L_{eq}(h)$ , are suitable for use in the environmental assessments conducted in project development. Appendix A also provides  $L_{eq}$ values for air compressors developed by EPA. Accurate equipment sound levels can best be developed by measurement. These values can be measured at any time, and if the equipment is well maintained, need only be measured once. Detailed evaluation of mitigation strategies generally require accurate equipment sound levels.

Equipment sound levels have two basic uses:

- They provide overall sound levels that can be used for comparing the noise emission levels from different makes or models of equipment.
- They can be used as emission models in noise prediction models.

To maximize their usefulness in these functions, the sound level must be in terms of the A-weighted, equivalent sound level measured over the equipment's work cycle. This requires a different measurement procedure for each of the three groups of equipment shown in figure 4. Unfortunately, standardized measurement procedures have not yet been developed. Until they are standardized, the following procedures can be used:

#### MOBILE EQUIPMENT

The Society of Automotive Engineers (SAE) test, J88a, "Exterior Sound Level Measurement Procedure for Powered Mobile Construction Equipment," sets forth a procedure for measuring the exterior noise level for the certification of construction equipment. The sound levels obtained during these tests "...are repeatable and are representative of the higher ranges of noise levels generated by the machinery under actual field conditions, but do not necessarily represent the average sound level over a field use cycle." Figure 5 illustrates the differences between the SAE J88a sound level, the instantaneous sound levels produced by the equipment, and the equivalent sound level. Thus, the first steps in determining the equivalent sound level of the equipment is to measure the sound level using the SAE J88a test procedure. A copy of this procedure is included in Appendix B.

- 1. The maximum sound level  $(L_m)$  measured during the duty cycle is assumed to be approximately equal to the SAE J88a Sound level  $(L_j)$  when  $L_m$  is measured at 15.2 meters.
- 2. The minimum sound level (L\_b) is measured during the duty cycle at the same distance as  $L_{\rm m}.$  In this figure, it is at 15.2 meters.

To convert the SAE J88a sound level, Lj, to an Leq, the time spent at the various sound levels must be accounted for. Since mobile equipment produces an instantaneous sound level curve that is rectangular in form, an approximate  $L_{eq}(h)$  can be calculated as follows (see Figure 5):

 $L_{eq}(h) = 10 \log[\frac{ta10 L_m/10 + tb10 L_b/10}{ta + tb}]$ (2-2)

Since  $L_m \approx L_i$  equation 2-2 reduces to

 $\mathsf{L}_{eq}(\mathsf{h}) = \mathsf{L}_{\mathsf{j}} + 10 \log \frac{\mathsf{ta}}{\mathsf{T}} + 10 \log (1 + \frac{\mathsf{tb}}{\mathsf{ta}} \ 10^{-(\mathsf{L}_{\mathsf{m}} - \mathsf{L}_{\mathsf{b}})/10})$ 

Where: Le

 $L_{eq}(h)$  is the A-weighted equivalent sound level assuming that the work cycle is repeated continuously over a one-hour period.

L<sub>j</sub> is the sound level measured using the SAE J88a test procedure.

 $\textbf{t}_a$  is the time spent at the maximum level (L\_m) during the work cycle.

 $L_m$  is the maximum sound level (approximately = to  $L_j$ ).

 $L_{\rm b}$  is the reduced sound level of the work cycle.

th is the time spent at the reduced sound level.

T is equal to  $t_a + t_b$  and represents the work cycle time.

In this manual the expression

$$10 \log \frac{ta}{T} + 10 \log \left[ 1 + \frac{tb}{ta} 10^{-(L_m - L_b)/10} \right]$$
(2-3)

will be called the equivalency factor (E.F.).

Therefore, equation 2-2 reduces to

$$L_{eq}(h) = L_j + E.F.$$
 (2-4)

Table 2 contains E.F.'s based on the difference between the maximum and minimum sound level,  $L_m$  and  $L_b$ , and the percent of time spent at the maximum level.  $L_m$  and  $L_b$  can be measured at any distance, but both values must be measured at the same distance. Note that  $L_m$  is approximately equal to  $L_j$  when  $L_m$  is measured at 15.2 meters. This procedure was chosen because it allows the calculation of  $L_j$  by a

standardized procedure that is readily available. The measurements of the absolute levels for  $L_m$  and  $L_b$  are not critical since the maximum difference ( $L_m$  -  $L_b$ ) is the parameter needed.

Lm-Lb					ta	/T					]

15	-9	-7	-5	-4	-3	-2	-2	-1	0	0	

Table 2: Equivalency Factors (E.F.) in dBA

Thus, to obtain an  $L_{eq}(h)$ , the following steps can be used:

- Determine L<sub>j</sub> using the SAE J88a test procedure or use the sound level given in Appendix A. (Note: The ARBA's sound levels in the Appendix are peak values measured at 15.2 meters and are approximately equal to L<sub>j</sub>. The EPA values are L<sub>eq</sub> values and need no adjustment.)
- Measure the maximum (L<sub>m</sub>) and minimum (L<sub>b</sub>) sound levels of the equipment in the field, at the same distance and concurrently, measure the time spent at these levels.
- 3. Subtract the minimum from the maximum sound level (approximately  $L_m L_b$ ) and compute the time the equipment operates at its maximum sound level over the cycle  $(t_a/T)$ .
- 4. Determine E.F. from Table 2.
- Compute L<sub>eq</sub>(h) using equation 2-4.

<u>Problem No. 3:</u> Compute the L<sub>eq</sub>(h) for a D-8 dozer which has an L<sub>i</sub> of 92 dBA. Under a normal work cycle, the dozer operates at a maximum sound level of 81 dBA for 30 seconds. This is followed by a reduced level of 70 dBA for 20 seconds.

Solution:	L <sub>an</sub> (h) ≃ L <sub>i</sub> + EF	
	$L_{m} - L_{h} = 81 - 70 = 11  dBA$	(Step 3)
	ta/T = 30/50 = .6	(Step 3)
	From table 2, E.F. = $-2$	(Step 4)
	$L_{eq}(h) = 92 - 2 = 90  dBA$	(Step 5)

#### STATIONARY EQUIPMENT-

The procedure used to determine the  $L_{eq}(h)$  for all stationary equipment, except impact equipment, is identical to that used for mobile equipment with one exception. For stationary equipment, Lj is measured using SAE J952b, "Sound Levels for Engine Powered Equipment." A copy of this procedure is included in Appendix B.

#### STATIONARY EQUIPMENT - IMPACT

There are no current procedures for measuring the Leq(h) for impact equipment. The measurement of sound levels for this type of equipment will require an impulse sound level meter. It is suggested that the instantaneous sound levels be determined over an extended period with particular attention given to peak values and that Leq(h) be computed from this curve. The measurement setup should conform to that used in SAE J952b. Additional information in this area will be developed by the Federal Highway Administration (FHWA) and furnished at a later date.

#### 2.3 OVERALL OR BOUNDARY NOISE LEVELS

Overall or boundary noise levels are the resultant sound levels produced by a particular construction operation at some point outside the construction site boundary. These values represent the sound levels heard by the community.

The construction of a highway is accomplished in several different phases. These phases can usually be characterized by the following:

- 1. Mobilization
- 2. Clearing and grubbing
- 3. Earthwork
- 4. Foundations
- 5. Bridge Construction
- 6. Base Preparation
- 7. Paving
- 8. Cleanup

Each of these operations occurs over some period of time. A simplified construction schedule using the above phases is presented in Figure 6.

#### Figure 6: Simplified Construction Schedule

Each phase will have its own noise level. Thus, the expression "construction noise" is rather meaningless unless it is expressed as the noise level during some phase of the construction operation.

Obviously, overall or construction noise measurements can only be made after construction starts. These values can be used for the following purposes:

- Assessing construction noise impacts.
- 2. Evaluating the effectiveness of different mitigation strategies.
- 3. Enforcing noise control regulations.
- 4. Evaluating the accuracy of noise prediction models.

Draft No. 7, "SAE Recommended Practice: Measurement Procedure for Determining a Representative Sound Level at a Construction Site Boundary Location," can be used to compute and approximate  $L_{eq}$ . A copy of this procedure is included in Appendix B. Users of this manual should recognize that this is a draft procedure.

#### CHAPTER 3

#### PREDICTION OF CONSTRUCTION NOISE

#### 3.0 BACKGROUND

The purpose of this chapter is to present a prediction methodology that can be used to estimate the construction noise levels associated with the construction of a highway. This prediction methodology serves two useful purposes.

- 1. It provides a mechanism for identifying potential noise impact areas prior to the start of construction.
- 2. It provides a mechanism for assessing the potential noise reduction resulting from certain mitigation strategies.

To completely fulfill the first purpose, the prediction methodology must provide as accurate an estimate of the construction noise level as the situation warrants. For example, during the early stages of project development, only a rough estimate of the expected construction noise effects is needed. This estimate is used to define general areas where construction noise may have an adverse effect. Conversely, a contractor preparing a bid on a project may need an accurate estimate of the expected construction noise levels. This estimate may indicate the extensiveness of abatement measures needed. This would likely influence the bid the contractor will submit.

To completely fulfill the second purpose, the prediction methodology must be sensitive to changes in the input parameters. This sensitivity allows the evaluation of those strategies for mitigating construction noise which are affected by the input parameters. Indeed, a knowledge of the relative effects of various mitigation measures will aid in the selection of the most cost effective abatement measure or measures.

The remainder of this chapter is organized into three sections. Section 3.1 presents the construction noise prediction methodology. Section 3.2 discusses how the prediction method can be used to identify construction noise impact areas. Section 3.3 deals with the evaluation of alternative measures.

#### 3.1 CONSTRUCTION NOISE PREDICTION METHODOLOGY

The basic methodology presented here for predicting construction noise is identical to that used in predicting highway traffic noise. It requires:

- 1. A noise metric to describe the magnitude of the construction noise level and its variation with time.
- 2. An emission model to determine the noise generated by the equipment at some reference distance.
- 3. A propagation model that shows how the noise level will vary with distance.

These three items can be related by the following expression:

$$L_{eq} \text{ equipment} = E.L. + 10 \log U.F. - k \log D/D_0$$
 (3-1)

Where:

 $L_{eq}$  equipment is the A-weighted, equivalent sound level at a receptor resulting from the operation of a single piece of equipment over some time period.

E.L. is the noise emission level of the particular piece of equipment based on its work cycle, i.e., recall equation 2.4: E.L. =  $Lj + E.F. @ 15.2 meters (D_0 = 15.2 meters)$ 

K is a constant that accounts for topography and geometric spreading.

D is the distance from the receptor to the piece of equipment.

 $D_0$  is the reference distance at which the noise emission level was measured from the piece of equipment.

U.F. is a usage factor that accounts for the percent time that the equipment is in use over the time period.

Our primary interest lies in the overall construction noise level produced by the simultaneous operation of several pieces of equipment. The overall construction noise level at some point is simply the sum (on an energy basis) of the individual contributions of each piece of equipment. Mathematically, the overall construction noise level at some point is expressed as:

 $L_{eq}(h)$  site = 10 log  $\sum_{i=1}^{n} 10^{\frac{L_{eq}(equipment)}{10}}$ 

(3-2)

Where:  $L_{eq}$  equipment is given by equation 3-1.

Ţ

L<sub>eq</sub> site is the A-weighted, overall equivalent construction noise sound level obtained by summing the individual equipment noise levels on an energy basis, and n is the number of pieces of equipment included in the summation.

The accuracy of Equation 3-2 depends upon the accuracy of the input parameters. This is shown in Table 3.

PROJECT STATUS	ASSUMED PARAMETERS	ACCURACY OF ESTIMATE ** (dBA)
Environmental Studies	Equipment, E.L., K., D., U.F.	Unknown
PS&E Preparation	Equipment, E.L.,* K., D., U.F.	Unknown
Contract Award	K., U.F.	+ or - 5
Under Construction	None	+ or -2

Table 3: Estimate of Accuracy of Prediction Method

\* Maximum values may be specified in plans.

\*\* Estimate based on limited data (see references 3, 6, 7, and 8).

Equation 3-2 can be used to identify potential construction noise impact areas or it can be used to evaluate various mitigation measures.

#### 3.2 IDENTIFICATION OF POTENTIAL CONSTRUCTION NOISE IMPACT AREAS

Equation 3-2 can be used to identify potential construction noise impact areas by providing an estimate of the expected construction noise level. The accuracy of this estimate is directly related to the accuracy of the input parameters. This can best be shown considering the two extreme situations, that is, where equation 3-2 provides its least accurate estimates and when it provides its most accurate estimate.

#### Least Accurate Estimate

For projects not under construction, equation 3-2 can be used to provide a rough estimate of the expected construction noise levels. Equation 3-2 provides its least accurate estimate when conditions or values must be assumed for all of the input parameters. This generally occurs during the early stages of project development. In an example of this situation, the following assumptions are used.

- One hour is selected as the time period of interest. This is reasonable since most construction equipment operates continuously for a one-hour period; the usage factor (U.F.) then becomes unity and 10 log U.F. is equal to zero.
- 2. Free field conditions are assumed, ground effects are ignored. Since each piece of construction equipment acts as a point source, the expression k log  $D/D_0$  reduces to 20 log  $D/D_0$ .
- 3. A representative noise emission level for a class of construction equipment is used. Note that E.L. =  $L_j + E.F.$ , i.e., the equipment hourly sound level at 15.2 meters is the noise emission level.
- 4. The equipment is assumed to operate on the centerline of the highway.

With these assumptions, equation 3-2 reduces to

$$L_{eq}(h)$$
 site = 10 log  $\sum_{i=1}^{n} 10^{L_{eq}(equipment)/10}$  (3-3)

Where:

 $L_{eq}(equipment) = (E.L. - 20 log D/D_0) equipment. \\ L_{eq}(h) site is the one-hour, A-weighted, overall equivalent construction noise level, and D_0 equals$ 15.2 meters.

One additional problem exists with the prediction of construction noise for projects not under construction. An assumption must be made about the numbers and types of equipment at the site. It appears at this time, that the overall construction noise level is governed primarily by the noisiest pieces of equipment.<sup>3</sup> The quieter pieces do not effect the overall level, but they do reduce the magnitude of the fluctuations in the noise level. Therefore, a rough estimate of the noise level need only incude the noisiest pieces of equipment expected at the site. Problem No. 4 illustrates this procedure.

Problem No. 4: Consideration is being given to the construction of a two-lane road on new alignment between two towns. The project has advanced to the point where a preliminary assessment of potential construction impacts is needed. Make a preliminary rough estimate of the hourly equivalent sound level that will be generated for each construction phase. Average distance from the centerline of the road to the ROW line is 30.5m.

- Solution Step 1: Identify the main construction operations or phases which must be performed to complete the project. This will require a simplified construction schedule which is shown in Figure 7.
- Step 2: Determine the types of equipment that will be needed to complete each construction phase identified in Step 1. Appendix A can be used to determine a representative noise emission level for each type of equipment.
- Step 3: Based upon the results of Step 2, prepare a list, complete with representative noise emission levels, of the two noisiest types of equipment that will be used in each phase. This list is shown in columns B and C, Table 4.
- Step 4: Use equation 3-3 to compute the L<sub>eq</sub>(h) for each type of equipment at 30.5 meters (distance to ROW line). The result of this calculation in column E, Table 4.
- Step 5: Compute the overall sound level for each phase using dB addition. The results are shown in Table 4, Column F.

Figure 7. Simplified Construction Schedule

Table 4:	Calculations,	Problem 4
----------	---------------	-----------

The second s	سنكي سنتكى عكاكب عبرك	The second s		The second division of	the second s
A	В	C <sup>1.</sup>	D	E	F

Cleanup	_			_	

1. E.L. = L<sub>J</sub> + E.F. where L<sub>J</sub> is the peak value from appendix A. (A representative E.L. was chosen and it was assumed that Lm-Lb>10 dBA and ta/T = 50%).

#### Most Accurate Estimate

Equation 3-2 provides its best estimate when all of the input data are measured, i.e., the project is under construction.

For projects under construction, some investigators have recently reported good agreement between measured and predicted noise levels ( $\pm$  2 dBA) using equations which have the general form of equation 3-2. However, to achieve this agreement, precise measurements of the following parameters were required:

- 1. The site topography.
- The noise emission level of each piece of equipment used at the site.
- The location of each piece of equipment while it was working.
- 4. The % of the time that the equipment was in use during the measurement period.

As a result of these measurements, accurate values were determined for the E.L., D and k for each piece of equipment operating at the construction site. This presents a problem in assessing construction noise impacts. Item 1 can be determined any time after the highway location is established. However, items 2, 3, and 4 can only be measured after construction begins. Consequently, the most accurate predictions of construction noise can only be made after construction begins. This is illustrated in Problem No. 5. <u>Problem No. 5</u>: The project discussed in example 4 has now progressed to the point where contractors are bidding on the project. The special provisions require that the exterior L<sub>eq</sub>(h) on school grounds be less than 75 dBA during school hours. A long fill is to be constructed adjacent to a school. One prospective contractor would like to use two dozers and three scrapers to construct this fill. The contractor has collected the following data on his equipment from previous projects.

	L	ե <sub>տ</sub> ,բթ	T <sub>a</sub> /T
Dozer 1	86	10	,5
Dozer 2	88	12	,5
Scraper 1	86	12	,3
Scraper 2	84	12	.3
Scraper 3	82	12	.3

Compute the noise emission level of the equipment and estimate the  $L_{\rm eq}(h)$  at the school,

<u>Solution</u> <u>Step 1:</u> The noise emission levels (L<sub>eq</sub>(h) at 15.2m) of the equipment is calculated by:

E.L. = L<sub>j</sub> + E.F.

The noise emission levels are shown in table 5.

	Li (dBA)	E.F. (Table 1)	NOISE EMISSION LEVEL (dBA)
Dozer 1	86	3	83
Dozer 2	88	3	85
Scraper 1	86	5	81
Scraper 2	84	5	79
Scraper 3	82	5	77

#### Table 5: Computation of Noise Emission Levels

Step 2: Assign at average location to each piece of equipment. This is shown in figure 8. Problem No. 5: (Continued)

Step 3: Compute the L<sub>og</sub>(h) for each piece of equipment using equation 3-1 and the overall construction noise level using equation 3-2. The results are shown in table 6. The construction L<sub>eq</sub>(h) of 80 dBA exceeds the specified goal by 5 dBA.

#### Figure 8: Construction Site

Table 6: Calculation, Problem 5							
A PHASE	b Equipment	C NOISE EMISSION LEVEL (dBA)	D DISTANCE FROM EQUIPMENT TO OBSERVOR (metors)	E EQUIPMENT L <sub>oq</sub> (h) AT RECEPTOR (dBA)	F OVERALL L <sub>eq</sub> (h) AT RECEPTOR (dBA)		
Earthwork	Dozer No. 1	83	183	61			
	Dozer No. 2	85	30	79			
	Scraper No. 1	81	152	61			
	Scraper No. 2	79	61	67			
	Scraper No. 3	77	46	67	80 dBA		

The 80 dBA value in column F was obtained by dB addition. The value could also have been determined by:

$$\begin{split} & L_{eq}(h) \text{ site } = \Sigma L_{eq}(h) \text{ equipment} \\ &= 10 \log \Sigma \, 10^{6.1} + 10^{7.9} + 10^{6.1} + 10^{6.7} + 10^{6.7} = 80 \text{ dBA}. \end{split}$$

#### 3.3 EVALUATION OF DIFFERENT MITIGATION STRATEGIES

Chapter 4 contains a detailed discussion of various mitigation strategies. The relative effects and effectiveness of a few of these strategies can be determined by the use of equation 3-2. This is done by holding all input parameters constant except the one affected by the particular mitigation strategy under study. Problem No. 6 illustrates how this is done.

<u>Problem No. 6</u>; Problem No. 5 indicates that the expected construction noise level exceeds the specified goal by 5 dBA. Evaluate different mitigation strategies that would give a reduction of 5 dBA.

Step 1: Analysis of table 6 indicates that Dozer No. 2 must be quieter if the desired goal of 75 dBA is to be met. If possible, one strategy would be to exchange Dozer No. 2 for Dozer No. 1.

Dozer No. 1:  $L_{eq}(h) = 83 - 20 \log \frac{30}{15.2} = 77 \text{ dBA}$ 

Dozer No. 2:  $L_{eq}(h) = 85 - 20 \log \frac{183}{15.2} = 63 \text{ dBA}$ 

 $L_{eq}(h)$  site = 10 log  $\left[10^{7.7} + 10^{6.3} + 10^{6.1} + 10^{6.7} + 10^{6.7}\right] = 78.1 \text{ dBA}$ 

Continued

The expected noise level exceeded the goal by 3 dBA. This strategy, by itself, is not enough.

Step 2: One mitigation strategy would be to replace Dozer No. 2. What would be an acceptable noise emission level for the replacement dozer 30 meters from the school? To answer this question, set the overall construction noise level equal to 75 dBA in equation 3-2 and solve.

$$\begin{split} & L_{eq}(h) \text{ site} = 10 \log \Sigma 10 L_{eq} \text{ (experiment)/10} \\ & 75 \text{ dBA} = 10 \log \left[ 10^{x/10} + 10^{6.3} + 10^{6.1} + 10^{6.7} + 10^{6.7} \right] \\ & \frac{75}{10} = \log \left[ 10^{x/10} + 10^{7.1} \right] \\ & 10^{7.6} - 10^{7.1} = 10^{x} \\ & 10^{7.28} = 10^{x/10} & 7.28 = x/10 \\ & 3 & L_{eq}(h) = 73 \text{ dBA at 30 meters.} \\ & L_{eq}(h) \text{ equipment} = E.L. - 20 \log \frac{D}{D_0} \\ & 73 \text{ dBA} = E.L. - 20 \log \frac{30}{15.2} \end{split}$$

E.L. = 73 + 6 = 79 dBA.

Conclusion; This strategy accomplishes the desired goal.

#### CHAPTER 4

#### MITIGATION

#### 4.0 BACKGROUND

The effective control of highway construction noise can be achieved in much the same manner as operational traffic noise is controlled by using a three-part approach. This consists of:

- 1. Control of the noise at the source.
- 2. Control along the path of the noise.
- 3. Control at the receptor.

The three-part approach was taken in developing this portion of the manual.

This chapter presents various state-of-the-art methods and techniques of noise control that can be used to reduce noise impacts associated with highway construction. Most of the measures presented have been contained in either construction specifications, special provisions, or supplemental contract documents. The measures can be employed independently or in combination, depending on the scope of the project and the resultant effects that are desired. Section 4.1 outlines the factors necessary for identification and selection of an appropriate abatement measure to control construction noise. Section 4.2 details various methods that can be used. This section includes five subsections. Each subsection explains the methodology in general terms and then presents specific control strategies found under these broad methodologies. The control strategy is described, the dB reduction resulting from implementation is provided if known, the advantages and disadvantages are given, and a brief discussion is provided listing other characteristics of the specific control strategy. Sample specifications or examples are provided for each methodology. (Note: Values used in the specifications may not be practical or achievable. The manual user is encouraged to develop his own criteria.)

#### 4.1 IDENTIFICATION AND SELECTION OF CONTROL MEASURES

After the potential impacts resulting from the construction activities have been established, the final step in the process is the selection of appropriate control measures to be implemented on the project. This can be approached in two stages:

- 1. Identification of feasible measures.
- 2. Final selection of mitigation strategies.
The first stage involves identification of control strategies that could be implemented that would bring about the desired reductions in noise impacts. Some of the factors that influence this identification process include:

1. Amount of reduction needed.

2. Local sentiment toward the proposed project.

3. Local noise ordinances.

4. Length of the construction period.

5. Effectiveness of control strategies.

6. Cost of control strategies.

On the basis of these and other factors, different noise mitigation strategies can be examined to determine what measures could be implemented for a specific project.

The last stage is the selection of a reasonable control strategy from the group examined in the identification stage. The measure or measures chosen should be weighed as to their benefits compared to their adverse effects. This weighing should take into consideration the monetary costs involved, problems with implementation of the measures, the sensitive receptors in the area, and the degree of noise reduction achievable.

#### 4.2 APPROACHES TO CONSTRUCTION NOISE CONTROL

Techniques for abating construction noise may vary from simple, inexpensive, easily implemented measures such as a requirement that all engines be equipped with a properly operating muffler, to more expensive, elaborate methods, such as equipment enclosures.

The control techniques outlined in this manual have been divided into five general categories. These categories have been further divided into different specific strategies. Figure 9 shows the breakdown and indicates how the remainder of this chapter is organized.

#### Figure 9: Control Strategies

It should be noted that a measure that may be suitable in one situation may not be suitable in another. Care should be taken in selecting the appropriate mitigation measure.

#### 4.2.1 <u>DESIGN\_CONSIDERATIONS\_AND\_SPECIFIED\_ALTERNATIVE\_CONSTRUCTION</u> <u>METHODS</u>

Noise impacts to sensitve receptors can occur on any project involving the construction or reconstruction of a highway facility. While the magnitude of these impacts may not be known precisely early in the project development stages, certain measures can be implemented during the design phase that can reduce the anticipated noise impacts.

These measures fall into three categories:

- 1. Design considerations and project layout.
- 2. Sequence of operations.
- Alternate construction methods.

The measure outlined are typically decided upon in the early stages of project development and included in the project plans and contract documents. Ideally, these strategies should be used in conjunction with other control methods.

#### Mitigation Group One

#### Mitigation Strategy One

#### DESIGN CONSIDERATIONS AND PROJECT LAYOUT

#### Description:

During the early design stages of project development, the sensitive noise receptors can be established. By identification of these receptors, steps can be taken to lessen the construction noise impacts. During location studies, natural and artificial barriers such as ground elevation changes and existing buildings can be considered for use as shielding against construction noise. During design, waste material dump and storage sites can be designated in areas where they also serve as noise barriers. Haul roads can be designated in locations where the noise impacts caused by truck traffic will be reduced.

#### dB Reduction:

Undeterminable at the design stages of project development.

#### Advantages:

These techniques provide early consideration of the impacts caused by construction activities. A better understanding of potential problems can be obtained.

#### Disadvantages:

Design changes and modification to project layout are not always practical or feasible. The magnitude of the dB reduction is difficult to determine prior to construction.

#### Discussion:

The responsibility for development of these measures is born by the designer. The problem is analyzed prior to preparation of plans and other documents. The measures to be implemented are then placed in the contract documents at the appropriate time in the project development.

#### Mitigation Group One

#### Mitigation Strategy Two

#### SEQUENCE OF OPERATIONS

#### Description:

When planning for construction of a highway project, certain steps can be taken in scheduling work operations. Several noisy operations can be scheduled concurrently to take advantage of the fact that the noise levels produced will not be significantly greater than the level produced if the operations were performed separately. Noise barriers ultimately to be constructed as part of the project for traffic noise abatement can be constructed in the initial stages of construction to reduce the noise impacts of the construction.

#### dB Reduction:

Undeterminable at the design stages of project development.

#### Advantages:

These techniques tend to lessen the ongoing impacts as the project progresses.

#### Disadvantages:

The magnitude of reduction is difficult to determine in the early planning stages. These measures may not be feasible or practical to implement.

#### Discussion:

These measures are typically used in conjunction with other control measures and are contained in the project documents.

#### Mitigation Group One

Mitigation Strategy Three

#### ALTERNATE CONSTRUCTION METHODS

#### Description:

Certain phases of highway construction work such as pile driving may produce noise levels in excess of acceptable limits, even when feasible noise reduction methods are used. The impacts resulting from this type of situation may be lessened or avoided by using alternate methods of construction. Generally, piling is driven using an impact hammer. This operation often produces excessive noise levels. Some reduction can be attained by various dampening and shielding methods discussed later. However, such methods rarely reduce the noise level to an acceptable level for the sensitive receptors close to the site. As an alternative to driving piles, vibration or hydraulical insertion can be used. Drilled holes for cast in place piles are another alternative that may produce noise levels significantly lower than the traditional driving method.

#### dB Reduction:

Significant reductions may be realized by using less noisy construction methods.

#### Advantages:

New and innovative methods of construction may be evolved by considering alternate methods.

#### Disadvantages:

Alternate methods produce their own noise impacts and may produce other adverse effects that have to be weighed.

#### Discussion:

Great care should be exercised in choosing alternate construction methods. The choice should be weighed as to its desirablility and feasibility (The measures decided upon are placed in the contract documents.)

### 4.2.2 SOURCE CONTROL

In devising construction noise control strategies, one important option is controlling the noise at the source. By specifying and/or using less noisy equipment, the noise impacts produced by construction of a highway facility can be greatly reduced or even eliminated. Source control requirements may have the added benefits of promoting technological advances in the development of quieter equipment.

Lessening the impacts from highway construction through source control techniques may be approached from three different ways:

- 1. Muffler requirements.
- 2. Maintenance and operational requirements.
- 3. Equipment emission level requirements.

These methods may be used separately or in combination in order to achieve the desired results.

#### Mitigation Group Two

Mitigation Strategy One

#### MUFFLER REQUIREMENTS

#### Description:

Most construction noise originates from equipment powered by either gasoline or diesel engines. A large part of the noise emitted is due to the intake and exhaust portions of the engine cycle. A remedy for controlling much of the engine noise is the specification and use of adequate muffler systems.

#### dB Reduction:

Reductions of 10 dBA or more can be achieved with optimal muffler systems. $^{6}$ 

#### Advantages:

Muffler requirements can be easily written in contract specifications, complied with and enforced. Inspection and enforcement are simple and easily done. They are effective in reducing engine produced noise at a low cost to the user.

#### Disadvantages:

Only effective for machinery powered by internal combustion engines. Does not effect operational noises, i.e., the noise produced by doing the work.

#### Discussion:

This noise control strategy would lead to replacement of worn mufflers and to retrofitting where mufflers are not in use. The user of the equipment has the responsibility to comply with the specifications provided in the contract documents. Routine field inspection will be necessary by both the contractor and enforcement personnel to ensure compliance.

# Example Specification: Mitigation Group Two - Source Control Mitigation Strategy One - Muffler Requirements

Sound Control Requirements. -- The Contractor shall comply with all Federal, State, and local sound control and noise level rules, regulations, and ordinances which apply to any work performed pursuant to the contract. In addition, each internal combustion engine, used for any purpose on the job or related to the job, shall be equipped with a properly operating muffler of a type recommended by the manufacturer. No internal combustion engine shall be operated on the project without said muffler.

> This specification is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation.

#### Mitigation Group Two

Mitigation Strategy Two

#### MAINTENANCE AND OPERATION OF EQUIPMENT

#### Description:

Poor maintenance of equipment may cause very high noise levels. Faulty or damaged mufflers, loose engine parts, rattling screws, bolts, or metal plates all contribute to increasing the noise level of a machine. Careless or improper handling and operation of equipment can also increase construction noise levels. Poor loading, unloading, excavation and hauling techniques are some examples of how lack of adequate guidance may lead to increased noise levels. Specifications can be written to require that all equipment be regularly inspected for deficiencies in the maintenance area. Likewise, specifications can require that equipment users be properly trained in the use of construction equipment.

#### dB Reduction:

Significant reductions are achievable through correction of maintenance problems and adequate training in the use of equipment.

#### Advantages:

Proper maintenance can result in less down time for equipment, thereby shortening the time the equipment may be required in the area. Repair costs resulting from improper maintenance can be avoided.

Proper training increases the efficiency of the operation as well as reducing the equipment produced noise levels.

#### Disadvantages:

There is no procedure for determining the magnitude of noise level decreases prior to operation of the equipment. This type of specification is weak when used by itself.

### Examples Specification: Mitigation Group Two - Source Control

Mitigation Strategy Two - Maintenance and Operation of Equipment

#### Noise Abatement Measures

The Contractor shall take such noise abatement measures that are necessary to comply with the requirements of this contract, consisting of, but not limited to the following:

Proper maintenance of all equipment to insure that noise is kept to a minimum.

Conducting truck loading, unloading and hauling operations so taht noise is kept to a minimum.

Routing of construction equipment and vehicles carrying spoil, concrete or other materials over streets that will cause the least distrubance to residents in the vicinity of the work. The Engineer shall be advised in writing of the proposed haul routes prior to the Contractor securing a permit from the local government.

> This specification is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation.

#### Mitigation Group Two

Mitigation Strategy Three

#### EQUIPMENT EMISSION LEVEL REQUIREMENTS

#### Description:

One of the most effective methods of diminishing the noise impacts associated with individual pieces of construction equipment is to employ less noisy machinery. This may be accomplished by specifying the quietest available equipment. Specifications can be provided that set an upper noise level for equipment, or they may be worded so as to group certain pieces into a single category and then set upper limits for that category.

Modifications such as dampening of metal surfaces is quite effective in reducing noise due to vibration. Another possibility is the redesign of a particular piece of equipment to achieve quieter noise levels. These modifications can usually only be done by the manufacturer or with factory assistance and can be costly, time consuming, and possibly ineffective in reducing the overall noise levels.

Another method of source control is employing shields that are physically attached to the particular piece of equipment. For stationary equipment and in cases where considerable noise reduction is required, enclosures have proven to be effective.

#### dB Reduction:

The reduction is controlled by the imposed limits and on the technical capabilities of the manufacturer or the equipment user. Noise reductions of up to 5 dBA can be achieved using dampening materials.<sup>6</sup>

Shields such as sound skins may achieve reductions of 20 dB at high frequencies and 10 dB in the middle frequency range. Sound aprons may achieve noise reductions up to 10 dBA.<sup>6</sup>

#### Advantages:

Significant noise reductions are achievable through emission level requirements.

New equipment emission level standards provided by the Environmental Protection Agency (EPA) can be specified for use for various types of construction equipment.

#### Disadvantages:

Noise level limits may be relatively difficult to set. Enclosures are not practical if they interfere with the machines function or impede air circulation or servicing of the piece of equipment. Modifications or adjustments to the particular piece of equipment may not be feasible because of the costs involved or technical limitations.

#### Discussion:

The EPA is in the process of developing noise emission level standards for new equipment. Standards are currently set for portable air compressors. Work is progressing in setting standards for wheel and crawler tractors, mobil earth moving equipment, and pavement breakers and earth drills. Once identified as a potential noise source, other construction equipment may be regulated. Source control techniques may be limited to employing shields that are physically attached to the particular piece of equipment. This type of shield is used to reflect, contain or absorb the noise emitted from construction machinery. Sound aprons and sound skins are two examples of such shields.

Sound aprons generally take the form of sound absorptive mats hung like curtains from the piece of equipment or on a specially built frame physically attached to the equipment. The aprons can be constructed of rubber, lead-filled fabric, or PVC layers with sound absorptive material covering the side facing the machine. Additionally, quilted material is currently available. Sound aprons are useful when the shielding must be frequently removed or if only partial covering is possible.

Sound skins are similar to sound aprons but differ in that they should be close fitting and air tight. Allowance must be made, however, to let air in for cooling. Any openings should be equipped with mufflers or angled air ducts lined with sound absorptive materials.

Enclosures for stationary work may be constructed of wood or any other suitable material and should be lined with sound absorptive material to prevent an increase of sound levels within the structure. They should be designed for ease of erection and dismanteling.

These source control methods are generally initiated or devised by the contractor in order to meet the noise emission level specifications or site noise levels. However, they may be actually specified in the contract documents.

### 2. Example Specification: Mitigation Group Two - Source Control

Mitigation Strategy Three - Equipment Emission Level Requirements

#### Construction Equipment Noise

Powered equipment. truck or power hand tools that produces a maximum sound level exceeding the following limits shall not be used during construction operations. The sound level limits specified are referenced to a distance of 50 feet from the equipment. Sound levels shall be measured in substantial conformity with Standards and Recommended Practices established by the Society of Automotive Engineers, Inc., including the latest revisions to SAE J366a and SAE J952b.

Where required by agencies having jurisdiction, certain noise producing work may have to be performed during other than regular working hours or only at specified periods.

	Type of Equipment	Sound Level Limits
a)	Construction and Industrial

# 3. Example Specification: Mitigation Group Two - Source Control

Mitigation Strategy Three - Equipment Emission Level Requirements

÷.

#### Noise Abatement Measures

The Contractor shall provide such equipment, sound-deadening devices, and take such noise abatement measures that are necessary to comply with the requirements of this contract, consisting of, but not limited to the following:

- (a) Shields or other physical barriers to restrict the transmission of noise.
- (b) Soundproof housing or enclosures for noise producing machinery.
- (c) Efficient silencers on air intakes of equipment.
- (d) Efficient intake and exhaust mufflers on internal combustion engines.
- (e) Line hoppers and storage bins with sound deadening material.

This specification is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation,

#### 4.2.3 SITE CONTROL

The ultimate purpose of construction noise control is to reduce the impacts on the sensitive receptors. In order to achieve this goal, another abatement technique is to specify and employ site noise limits and noise control measures. Site noise control typically involves limiting the amount of noise reaching the sensitive receptors. Specifications may be written that set certain limits at the receptors, thus allowing the equipment user to devise his own methods for meeting the requirements or they may directly specify certain actions that may be taken to achieve a noise reduction at the receptors.

#### Description:

In order to meet site or receptor limits, various methods to reduce noise impacts have proven successful. The methods described are normally used in conjunction with other mitigation strategies to achieve an overall noise level reduction at identified locations.

One way to reduce the noise impacts at sensitive receptors is to operate stationary equipment such as air compressors, generators, etc. as far away from the sensitive receptors as practical. Pit areas or excavate portions on the job site may provide suitable locations for stationary construction activities and at the same time serve as noise barriers.

In some cases, activities such as form building, bridge and culvert construction, or other work involving stationary activities can effectively be accomplished inside an enclosure in order to reduce the noise impacts. In all cases where enclosures and excavation are involved, proper ventilation, access, egress and safety for the construction worker must be considered and maintained.

In some situations, such as in urban areas or on isolated sections of a project, it may be beneficial and indeed necessary to construct barriers adjacent to the work area.

#### dB Reduction:

The reduction in noise levels will vary with the method employed. Measurements are necessary to determine the exact levels.

#### Advantages:

Site noise limits are useful and advantageous because they tend to allow the contractor more freedom in developing means to reduce the noise impacts to the surrounding areas.

If properly designed and erected, barriers can not only be very effective in reducing sound propogation from the work area, but can also serve as physical, safety barriers to the site.

#### Disadvantages:

It may become very complex to set reasonable yet effective limits. Limits can not be set so low as to make the specification impossible or impractical to meet. Limits should not be set so high as to make the specification meaningless.

This type of control is extremely difficult to enforce, particularly when the noise metric involves long term averaging, i.e.,  $L_{eq}$  (24).

In employing some site control methods, the noise levels in certain areas within the construction area boundaries may be increased which will in turn affect project personnel working in the area.

Some measures may be costly and not easily implemented. Care must be taken to insure that if some type of barrier is used it will not create a hazard for the traveling public or the project personnel.

#### Discussion:

Special prefabricated panels are currently manufactured that can be relatively easily moved and erected. These may be ideally suited for controlling overall site noise in some situations.

# <u>Example Specification</u>: Mitigation Group Three - Site Control Mitigation Strategy One - Site Control

The noise level from the Contractor's operation shall not exceed:

- 1. x dBA @ y metres;
- 2. y dBA @ ROW or
- 3. z dBA @ t receptor

This requirement in no way relieves the Contractor from responsibility for complying with local ordinances regulating noise level.

The Contractor shall purchase, modify, and operate equipment; erect barriers; attach aprons and skins; etc., and take any other measures necessary to meet the specified site noise limits.

Said noise level requirement shall apply to all equipment on the job or related to the job, including but not limited to trucks, transit mixers or transient equipment that may or may not be owned by the Contractor. The use of loud sound signals shall be avoided in favor of light warnings except those required by safety laws for the protection of personnel.

Full compensation for conforming to the requirements of this section shall be considered as included in the prices paid for the various contract items of work involved and additional compensation will be allowed therefore.

> This specification is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation.

#### 4.2.4 TIME AND ACTIVITY CONSTRAINTS

Construction activity and the associated noise can be quite annoying and disruptive during leisure hours, during the hours of sleep, and, any time where loud continuous noises may effect certain special activities. Time constraints and use of equipment regulations can be very effective in reducing the impacts caused during these hours of the day.

#### Description:

During leisure hours and during periods of sleep, disturbance from equipment use can be kept to a minimum. The basis for the noise control strategy is to limit the times that certain noise construction activities may be prosecuted. Generally, this can be accomplished by requiring the contractors to perform such work during daylight hours when the majority of individuals who would ordinarily be affected by the noise are either not present or are engaged in less noise sensitive activities or limit nighttime work to that which is less than certain specified values.

Loud continuous noises around such critical noise receptors as schools, hospitals, etc., are disturbing at all times. Time constraints that restrict the construction activity to limited time periods can be effective in lessening these impacts.

#### dB Reduction:

During hours that the activity is restricted there is no impact associated with the particular activity.

#### Advantages:

.Time constraints are effective in reducing noise impacts during critical periods of the day.

#### Disadvantages:

Time limitations may increase the overall length of time necessary to complete the project.

# <u>Example Specification</u>: Mitigation Group Four - Time Constraints Mitigation Strategy One - Time Constraints

<u>Noise Control</u> - The Contractor's construction operations shall be performed in such a manner that noise levels established for designated land use activities and time periods, when measured at designated distances from the Right-of-Way, will not exceed those shown in Table I-1. However, this provision is not applicable if the ambient noise (noise caused by sources other than construction operations) at the doing of reception is in excess of the construction noise level at that point.

The Department reserves the right to monitor construction operations as deemed necessary. In the event construction noise level(s) exceeds those levels shown in Table I-1, the Contractor shall take such action as necessary to conform with this provision prior to proceeding with his operation. The Contractor shall be responsible for all costs arising from delay of operation(s) due to non-compliance with this noise control provision.

LAND USE ACTIVITY	MAXIMUM ALLOWABLE EXTERIOR NOISE LEVELS dB (A)	APPLICABLE TIME PERIOD
residential, hospitals,	88	ба.т 8 р.т.
nursing homes, schools,		
churches, libraries,		
offices, parks, picnic		
areas, recreational		
areas, playgound,		
active sport areas	67	8 p.m 6 a.m.

#### TABLE I-1 MAXIMUM ALLOWABLE CONSTRUCTION NOISE LEVELS

This specification is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation.

¢

# 2. Example Specification: Mitigation Group Four - Time Constraints

Mitigation Strategy One - Time Constraints

#### Mobile Equipment

Sound levels from mobile construction equipment shall not exceed the following:

#### Residential Areas

Daily, except Sundays & Legal Holidays 7:00 a.m. to 7:00 p.m.	85 dBA
Daily, except Sundaya & Legal Holidays 7:00 p.m. to 7:00 a.m.	65 dBA
7:00 p.m. Saturday to	65 dBA

7:00 a.m. Monday & Legal Holidays

#### Business - Commercial Area:

Daily, including Sunday & Legal Holidays, all hours, a maximum of 90 dBA.

#### Stationary Equipment

Sound levels from stationary equipment shall not exceed the following:

#### Residential Areas

Daily, except Sundays & Legal Holidays 7:00 a.m. to 7:00 p.m.	70 dBA
Daily, except Sundays & Legal Holidays 7:00 p.m. to 7:00 a.m.	55 dBA
7:00 p.m. Saturday to 7:00 a.m. Monday & Legal Nolidays	55 dBA

#### Business - Commercial Areas:

Daily, including Sundays & Legal Holidays, all hours, and maximum of 75 dBA.

This specification is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation.

The values given may not be practical or achievable.

#### 4.2.5 COMMUNITY AWARENESS

Although not a physical method of noise abatement, public relations and community awareness is a positive method of lessening the impacts of construction-related noise and disturbances. There are numerous instances during the various phases of activity where noise reduction is not feasible or warranted. In these cases, it is especially helpful for the impacted property owners to be made aware of the upcoming activity. It is also possible to forestall a great deal of adverse community reaction by implementing early public involvement into the project.

#### Description:

There are various techniques that may be employed to inform the public of upcoming noise impacts related to the construction activity. Depending on the scope of the project, the lengths of time involved in a particular phase of work, and the degree of unavoidable impact, the methods used can be as simple as distributing flyers to the adjacent property owners or may be as complex as conducting public informational meetings. The most important consideration in any method chosen is early communication. The scope of the proposed work and when possible, the time span of the activity should be spelled out in order to allow residents to plan their activities accordingly.

#### Advantages:

This method promotes better relations between the public, the contracting agency and the contractor.

#### Disadvantage:

This method may not physically reduce the construction noise impacts.

#### Discussion:

The contracting agency should also take an active role in insuring that the communication lines are open and the public is properly informed of upcoming construction activity. This may be accomplished by seeing to it that all questions and inquiries from the general public are courteously and reasonably responded to.

The highway agency may require the contractor to alert the public in a timely manner in the contract documents or the agency may take on the public relations function itself.

# Example: Mitigation Group Five - Community Awareness Mitigation Strategy One - Public Relations

#### TO THE PUBLIC

Our purpose in distributing this curcular is to keep you informed concerning the Metro Construction in your neighborhood. As is METRO policy, it is our aim to cooperate with property owners, tenants, businessmen, businesswomen and ordinary citizens who are directly affected or inconvenienced by the work. In turn, we would appreciate your indulgence during the construction period. Inquires should be directed to Resident Engineer.

Description of Work: Drill and blast 20' diameter shaft 150' deep through rock. Blasting will be monitored by instruments to insure against any damages to adjacent buildings. Duration of Work: April 1 to February 1.

Days of Operation:

Monday through Friday 7:00 a.m. to 10:00 p.m.

This is provided for example purposes only. The contents do not necessarily reflect the official views or policy of the Department of Transportation.

#### APPENDIX A

#### CONSTRUCTION EQUIPMENT NOISE LEVELS AND RANGES

The noise emission levels listed for various types of construction related machinery are, with the exception of the compressor data, based on limited samples. The values are presented in order to give the reader a basic understanding of where particular pieces of machinery fit on a noise-range spectrum of levels. Additional data and updated material should be added when it becomes available.

The majority of the data was provided by the American Road Builders Association. This data was taken during a 1973 survey in which member contractors were asked to secure readings of noise exposure to operators of various types of equipment. Additionally, the contractors were asked to take readings at 50 feet from the machinery. These 50feet peak readings are provided in the appendix. The data was produced under varying condition and degrees of expertise, however, the values are relatively consistant.

The data provided for portable air compressors was taken from the U.S. Environmental Protection Agency publication EPA 550/9-76-004 which was used in the development of the final Portable Air Compressors Regulation. The data represents average noise level readings taken at 7m(23 ft.) using the CAGI/PNEUROP measurement method.

## APPENDIX B

# Measurement Procedures

The measurement procedures referenced in the text are provided for easy referral.

#### EXTERIOR SOUND LEVEL MEASUREMENT PROCEDURE FOR POWERED MOBILE CONSTRUCTION EQUIPMENT—SAE JBBa

#### **SAE Recommended Practico**

Report of Vehicle Sound Level Committee approved November 1972 and fair respect fune (91). Retrongile matement availability

1. Scope-This SAE Recommended Practice sets furth the instrumentation A Scept—This SAE Recommended Practice sets forth the instrumentation and procedure to be used in measuring creterio sound levels for the certifica-tion test of powered mobile construction equipment of 20 rated bhp and over. It is not intended to cover operation of safety devices (such as backup alizmi), ali compresson, jack harmera, pile drivers, pavement brakers, and machine ery disigned primarily for operation on highways or within factories, siteraft, or recreational vehicles such as nownobiles and boats. The sound levels obtained by using the test procedures set forth in this SAE Recommended Practice are repeatable and are representative of the higher range of sound levels generated by the machinery under actual field operating conditions, but do not necessarily represent the average sound level over a field use cycle. 2. Instrumentation 2. Instrumentation

2.1 A sound level meter which meets the Type I or SIA requirements of American National Standard Specification for Sound Level Meters,

the American National Standard Spectrolation and Level 51.4-1971, 22 As an alternative to making direct measurements using a sound level meter, a microphone or sound level meter may be used with a magnetic tape recorder and/or graphic level recorder or indicating instrument, providing the system meets the requirements of SAE Recommended Practice J184 Quali-prime a Sound Data Acquisition System. 23 An acoustical calibrator (see paragraph 4.2.4-accuracy within +0.5 dB).

2.5 An accuracy within 25.5 dB.
 2.4 A microphone winduces shall be used that does not permit the effect on the microphone and frequency response to exceed ±0.5 dB to 5 kHz and ±2.0 dB to 12 kHz.

2.5 An anemometer or other device for measurement of ambient wind speed and direction (accuracy within ±103).

2.5 A power source rpm indicator (accuracy within ±2%), 2.7 A thermometer for measurement of ambient temperature (accuracy within ±1\*), 2.8 A barometer for measuring atmospheric pressure (accuracy within

. . .

#14). 3. Procedure 3.1 Test Site-The test area shall consist of a flat open space free of any

3.1 Test Site—The test area shall consist of a flat open space free of any large reflecting surfaces, such as a signboard, building or hillidie, located within 30 m (100 ft) of either the microphone or the machinery being meas-ured (see Fig. 1). It is recommended that measurements be made only when the wind speed is below 19 km/b (12 mph). 3.1. The mininum measurement area (see Fig. 1) shall consist of the triangle formed by the microphone location, points A and B, and the rectan-gle formed by points A, B, C and D. Boith designated areas shall be smooth concrete or smooth and scaled asphalt or a similar hard and ismooth surface. The rectangle formed by points C, D, E and F shall consist of hard-packed carth. The places between the microphone location and line AB and planes encompassed by points A, B, C, F, E and D shall form a continuous, uniform plane. If a minimum measurement area test as is ia used, it will require reorientation of the machine for each major surface measurement during the stationary tests, and the mochine (for stationary tests and terborate stars) and the mochine for stationary tests and the mochine of practice directions. A late microphone for the series of practice test conditions with the machine is one position for stationary tests and driving by in only one direc-tion for the moving test. tion for the moving tests.

3.1.2 Because by an in the vicinity of the construction machinery or micro-

phone, not more than one person, other than the observer reading the meter, shall be within 17 m (56 ft) of the construction machinery and 1.8 m (6 ft) of the measuring microphone, and that person shall be directly behind the observer who is reading the meter, on a line shrough the microphone and the

observer (see Fig. 1). 3.1.3 The ambient sound level due to source) other than the construction machinery being meanined including wind effects) shall be at least 10 dB lower than the sound level of the machinery being measured. (See paragraph 3.3.3.)

3.3.3.1 The surface between and under the construction machinery and microphone shall be smooth and free of acoustically absorptive material, such **61 (** OF STASS.

a new of grass. 3.1.5 For all atasionary tests the machinery shall be located on the hard utface area formed by points A, B, C and D in Fig. 1. 3.1.6 Moving Texts

3.1.6.1 For moving tests of all rubber tired machines, the path of travel ahall be across the area defined by points A, B, C and D in the directions shown in Fig. 1.

3.1.6.2 For moving tests of all steel wheel, steel drum or track-type machines the path of travel shall be across the area defined by C, D, E and F in the directions shown in Fig. 1. 3.2 Test Barolina

3.2 Tests Required

3.2 Tests Required
(a) For mobile construction machinery that is used primarily in a stationary mode, test per paragraphs 3.2.1.1, 3.2.1.2, and if applicable 3.2.1.3.
(b) For tell-propelled construction machinery that is used primarily in a mobile mode, test per paragraphs 3.2.1.1, 1.2.1.2, 3.2.1.3 and 3.2.2. For construction machines which have an auxiliary power source, such as a truck mounted crane, the main engine and auxiliary nomer source, such as a truck mounted crane, the main engine and auxiliary constructions 3.2.1.8 and 3.2.1.2. with the other engine shall be run separately during test 3.2.1.3 only the auxiliary engine shall be run and only the main propulsion engine run during the test prescribed in 3.2.2. For combined construction machinery (such as small loader with backhoe) test per paragraphs 3.2.1.1, 3.2.1.2, 3.2.1.3 and 3.2.2.
5.2.1 Stationary Tests with Ground Propulsion Transmission Shift Selector

3.2.1 Stationary Tests with Ground Propulsion Transmission Shift Selector in Neutral Positio

3.3.6 For stationary tests, record the sound level obtained at a distance of 15 m (50 ft) normal to the centers of the four major surfaces of the equipment at the microphone height. Generally, four major surfaces refer to front, rear, 3.2.1.1 Operate all mobile construction machinery engines at no load with all component drive systems in neutral position and maximum governed apeed (high idle at no load) at a stabilized condition. and sides of an imaginary hox that would just fit over the machine but doe In the case of a crane or an excavator, the upper (revol ing superstructure) fore-and-aft centerline should be in line with the lower fore-and-aft centerline.

aperd (nigh lide at no load) at a statusted condition. 3.2.1.2 Operate all mobile construction nuclinitry engines at no load with all component drive systems in neutral position through the cycle "low idlemaximum governed speed (high idle at no load) low idle" as rapidly as possible, but allowing the engine to stabilize for at least 10 s at maximum governed speed (high idle at no load, before it is permitted to return in low idle.

3.2.1.3 With the engine at the maximum governed speed (high idle at nu load) in a stabilized condition, activate the appropriate hydraulic circuits, mechanical, electrical, hydrostatic, or torque converter drive systems to cycle the major components or component from the mast retracted and, or lowered position to fully extended and/or maximum height position and then back to posi original position. This cycling should be done as fast as practical, taking into consideration all the pertinent safety factors that can be accomplished without blowing relief valves. For safety reasons and undesirability of change of location of major noise tource in relation to microshone, a major portion of the nubile machine, such as the tractor of a scraper unit, drum of a compac-tor, or the upper rotational structure of an excavator, shall not be moved or closed to a scheme to the structure of an excavator, shall not be moved or

tor, or the upper minimal structure of an excavator, shall not be moved or placed in a vibrancy mode of operation during this stationary machine test. 3.2.2 Construct Series Movino Tar-Self propelled construction machinery shall be operated in a forward intermediate gear ratio at no load at a location as specified in paragraphs 3.1.6.1 or 3.1.6.2. The power source shall be operated at full governor control setting. Intermediate is intended to mean second gear ratio fur machines with three or four gear ratio, at hold at a for machines with five or six gear ratio; fourth gear ratio for machines with seven or eight gear ratios, etc. (Gear ratio refers to overall gear reductions.) If there is a problem with the transmission shifting up or down in this phase of this test; one gear lower or higher may be used to eliminate the problem. Hydrostatic or electric drive machinery will be operated as near as possible to one-half its maximum ground speed. Machinery that has major nois-generat-ing components which could be used at the above ground speed, such as on an elevating scraper or on a vibrating compactor, shall have these major compo-nents in operation during this moving test. nents in operation during this moving test.

3.3.1 The microphone shall be located at a height of 1.2 m (4 ft) above the

wind plane. 3.3.2 The sound level meter shall be set for slow response and the A-weight-

a network. 3.3.3 The ambient wind-speed and direction, ambient temperature, atmos pheric pressure, and ambient A-weighted sound level shall be measured and recorded at the height of 1.2 m (4 ft) and within at least 3 m (10 ft) of the one specified location of the microphone as shown in Fig. 1.

3.3.4 The stabilized maximum governed engine speed shall be measured

3.3.5 The sound level meter needle movement shall be observed during each teil sequence at the specified microphone location. The highest value observed, disregarding sounds of short duration that are out of character with the test on the machine, (example) impact sound such as bucket rack against

the test of the machine, (stample) impact sound such as bucket rare against upp, shall be recorded for each test sequence. For stabilized test conditions (3.2.1.1) a single reading shall be recorded for each measurement point. For cycling and moving test conditions (3.2.1.3, 3.2.1.3 and 3.2.2 a minimum of three readings shall be taken for each measuring point. If none of these readings that be taken for each measuring point. If none of these readings that be taken the na diditional readings shall be taken until there are two that are within 2 dB of each other, the reported value of the taken taken the taken taken taken the taken taken taken taken the taken take

unit inter are two that are winnin 2 do or each bind; the reported value while the average of these two values that are within 2 db of each other. If there are two pairs of readings that are within 2 db of each other, report the average of the higher pair. The final result for each test mode shall be the highest reading for stabilized test conditions and the highest average for the clic or moving tests and must include the location of the micropi

not include attachment items such as buckets, dozers, and booms (see Fig. 2)

Operate the machine in a manner as specified in paragraphs 3.2.1.1, 3.2.1.2

3.3.7 For moving tests, take measurements at a distance of 15 m (50 ft) neasured in a direction normal to a major side surface which is parallel to the

machine path, as shown in Fig. 1. Operate the machine in a manner specified

in paragraph 23.2. 3.38 The final reported sound level per this SAE Recommended Practice thall be the highest of the reported values obtained in paragraphs 3.36 and 3.37; the test report shall include the test mode, the machine operating conditions during the reported test mode, the stabilized maximum governed

engine speed, the location of the microphone in relation to the construction machine, the surface dewription over which the machine operated and the sound level measurements were made.

4.] It is recommended that persons technically trained and especienced in the current techniques of sound measurements select the instrumentation.

4.2 Proper use of all test instrumentation is essential to obtain valid measurements. Operating manuals or other literature (unnished by the instru-ment manufacturer should be referred to for both recommended operation of the instrument and precautions to be observed. Specific items to be considered

4.2.1 The type of microphone which shall be oriented with respect to the that the sound strikes the disphragm at the angle for which the

FIG. 2-MAJOR SURFACE OUTLINES

#### SOUND LEVELS FOR ENGINE POWERED EQUIPMENT-SAE J952b

Report of Communition and Industrial Blackmery Technical Committies approved May 1966 and last revised by Vehicle Sound Level Committee January 1969 Eduard change June 1973

Introduction—This SAE Standard establishes maximum sound levels for engine powered equipment and describes the test proceedure, environment, and instrumentation for determining these sound levels. It does not include machinery designed for operation on highways or within factories and build-

ing areas. 2. Maximum Sound Levels-See paragraph 3.2 and Table 1.

2. Instrumentation 3.1 Assund level meter which meets the requirements of International Electrotechnical Commission Publication 179, Precision Sound Level Meters.

3.2 A sound level calibrator (see paragraph 5.5). 3.3 A calibrated windscreen (see paragraph 5.4).

6. Proceedings of the state of the paragraphic of a flat open space free of any 4.1 Test Sile—The test area shall consist of a flat open space free of any large reflecting surfaces such as a siphoard, building, or hillside located within 100 ft of either the microphane or the equipment being recorded. 4.1.1 Bytanders may have an appreciable influence on meter response it such persons are in the vicinity of the equipment of the microphane. No person other than the observer reading the meter shall be near the microphane.

prome. 4.1.2 The ambient sound level (including wind effects) due to sources other than the equipment being measured shall be at least 10 dbA lower than the level of the tested equipment.

SAE Standard

4.1.3 The path of equipment travel shall be over a surface which is typical of the particular machine application. 4.2 Equipment Operations—Operate the equipment at the combination of load and speed which produce the maximum sound level without violating the manufacturer's operation specifications. 4.3 Measurements.

4.5 Measurements 4.3.1 The microphone shall be located at a height of 4 ft above the ground

plane. 4.3.2 The meter shall be set for "fast" response and the A-weighting net-

4.3.2 The meter shall be set (10<sup>-1</sup>/ht<sup>-1</sup> reporte and the highest sound level work. 4.3.3 For equipment which is not traveling, record the highest sound level obtained at 50 ft from the nearest surface of the equipment. 4.3.4 For traveling equipment, take measurements at 30 (normal from the centerline of the path of stright) line travel. The applicable reading will be the highest sound level obtained from the loadest side as the equipment moves along the line of travel. 4.3.5 The sound level which is reported shall be the average of the two highest applicable readings with are within 2 dB of each other.

#### DRAFT NO. 7

#### SAE RECOMMENDED PRACTICE: MEASUREMENT PROCEDURE FOR DETERMINING A REPRESENTATIVE SOUND LEVEL AT A CONSTRUCTION SITE BOUNDARY LOCATION

## 1. <u>Scope</u>

This SAE Recommended Practice sets forth procedures and instrumentation to be used for determining a representative sound level during a representative time period at selected measurement locations on a construction site boundary. It concerns the community adjacent to the construction site, and it is not intended for use in determining occupational hearing damage risk.

## 2. Introduction

The procedure set forth in this document may be used by construction site management for self regulation and construction site planning or by state and local officials for the enforcement of construction site noise regulations. As is demonstrated in the companion document (Reference 1) to this recommended practice, the representative sound level obtained using this procedure approximates the "energy" equivalent sound level,  $L_{eq}$ , (Reference 2) obtained from more sophisticated data acquisition and analysis techniques. Use of this recommended practice provides sound level data representative of the complex time-varying sounds emitted by construction activities which may be ap-

plied using various methods (Reference 1) to estimate community reaction to the construction activity.

## 3. Definitions

Construction Site - That area within the defined boundaries of the project. This includes defined boundary lines of the project itself, plus any staging area outside those defined boundary lines used expressly for construction or demolition.

Boundaries of the Construction Site - The outermost limit lines of the construction site.

Noise Sensitive Area - Inhabited property such as that used for public, commercial, religious or educational purposes, or home dwellings, parks, and other special purpose areas where the background ambient sound is less than the construction site sound level.

Background Ambient Sound - The all encompassing sound associated with the given environment, when the construction site is inactive, being usually a composite of sounds from many sources far and near.

Representative Sound Level,  $\overline{L}_A$  - It is the average of sound level samples accomplished in accordance with procedures outlined in 6.1.1.-6.1.5.

#### 4. Instrumentation

- 4.1 A sound level meter which meets Type 1 requirements of the American National Standards Specifications for sound level meters, S1.4-1971 (Reference 3).
- 4.2 As an alternative to making direct measurements with the sound level meter, a microphone or sound level meter may be used with a magnetic tape recorder and/or graphic level recorder or data analysis instrumentation (either analog or digital) providing the system meets the requirements of SAE Recommended Practice: Qualifying a Sound Data Acquisition System, J-184 (Reference 4).
- 4.3 An acoustic calibrator with an accuracy of 0.5 decibel (see Paragraph 7.2.4).
- 4.4 A windscreen (see Paragraph 7.3).
- 4.5 An anemometer with ±10 percent accuracy.

#### 5. Site Determination

- 5.1 Obtain specific drawings, survey stake locations, and other pertinent information in order to sketch the boundaries of the construction site and noise sensitive areas on a facsimile of Figure 1.
- 5.2 Obtain information in sufficient detail necessary to determine location and activity pattern of the construction site during the period used for measurement,

as well as the locations of noise sensitive areas, in order to aid in the selection of sound level measurement locations.

15 January 1976 Draft No. 7

## 6. Measurement

- 6.1 Sound level measurements at construction site boundary adjacent to noise sensitive areas shall be taken in the following manner:
  - 6.1.1 Calibrate the sound level meter before and after each measurement period, using an acoustic calibrator.
  - 6.1.2 Locate the microphone at five feet (1.5m) above the ground and, if practical, 10 feet (3.1m) from walls, buildings, or other sound reflecting structures when they appear at the construction site boundary. When circumstances dictate, measurements may be made at greater distances and heights and closer to walls, providing these facts are noted.
    6.1.3 Set the sound level meter to the A-weighting
    - network and slow response. Observe the sound level meter during a 10 <u>+</u>2 second sampling period at the <u>start</u> of each minute and one-half minute for any representative 30minute period of construction activity. If,

during any of these observations, the measurements are affected by any intrusive noise sources outside the construction site, such as aircraft, emergency signals, and surface transportation, measurements made during these periods should not be considered, but the number of one-half minute observation periods should be extended until 60 valid measurements are obtained.

On/off highway vehicles, such as dump trucks, truck/mixers, etc., which occasionally enter, operate on, and leave the site, shall be considered as part of the construction activity while within the site boundaries. However, pass-by of such vehicles, in the area of the measurement location causing difficulty in obtaining valid measurements, shall be considered as intrustions, and handled as in the preceding paragraph. An alternative measurement system, Paragraph 4.2, may be required to augment the direct measurements for these construction site conditions.

6.1.4

Tabulate the maximum values,  $L_A$ , observed during the sample period, using a data sheet such as shown in Figure 2.

6.1.5

Determine the representative sound level,

$$\bar{\mathbf{L}}_{\mathbf{A}}$$
, using:  
 $\bar{\mathbf{L}}_{\mathbf{A}} = (\sum_{\mathbf{L}} \mathbf{L}_{\mathbf{A}})/n$ 

Arithmetic average of L<sub>A</sub> values.

 $L_A$  values: those sound levels which fall within a range of from 6 decibels less than the maximum level to the maximum level.

n: the number of  $L_A$  values used for computing the arithmetic average.

The use of this technique provides a result which is comparable to "energy averaging" all of the observed values. Corrections may be applied (see Table 1) which results in a computation of L<sub>eq</sub> for the representative measurement period.

## 7. General Comments

7.1 It is often desirable to obtain the background ambient sound level on the same day as the sound survey to obtain representative construction site sound levels. It is suggested that this be accomplished when the construction site is inactive, such as before start-up, during the luncheon break, or after shut-down. The above procedure (6.1.1-6.1.5) should be used. 7.2 It is recommended that persons technically trained and experienced in the current techniques of sound measurements select the equipment and conduct the tests.

RAFI

15 January 19 Draft No. 7

- 7.3 Proper usage of all test instrumentation is essential to obtain valid measurements. Operating manuals or other literature furnished by the instrument manufacturer should be referred to for both the recommended operation of the instrument and precautions to be observed. Specific items to be considered are:
  - 7.3.1 The type of microphone, its directional response characteristics, and its orientation relative to the ground plane and source of noise.
  - 7.3.2 The effects of ambient weather conditions on the performance of all instruments (for example, temperature, humidity, and barometric pressure). Instrumentation can be influenced by low temperature and caution should be exercised.
  - 7.3.3 Proper signal levels, terminating impedances, and cable lengths on multi-instrument measurement systems.

7.3.4 Proper acoustical calibration procedure, to include the influence of extension cables,

etc. Field calibration shall be made immediately before and after each test sequence. Internal calibration means is acceptable for field use, provided that external calibration is accomplished immediately before or after field use.

- 7.4 A microphone windscreen shall be used provided that its effect on the total sound level measuring system does not degrade the system below the requirements of ANSI S1.4-1971, for Type 1 sound level meters. It is recommended that measurements be made only when wind velocity is below 12 mph (19 km/hr).
- 7.5 Measurements should not be made if significant changes in extraneous and non-construction related noise-making activities or patterns occur during the sampling period. Examples of changes in noise-making activities or patterns which affect the data are:
  - Nearby noise sources, such as power mowers, pavement breakers, brush cutters, or power saws.
  - (2) Changes in vehicular traffic flow, such as closed street, detours; or shift-change periods near industrial plants.
